Pre-registered prediction: TESS Sector 114 transits of the 5.45-day candidate on TOI-913 (TIC 407126408)

Josh Gold
Independent researcher, Acton, Massachusetts, USA

Registered 11 October 2026, before Sector 114 is observed (planned 2027 February 13 – March 14).
Companion to doi:10.5281/zenodo.23290579

Purpose

The candidate in the companion preprint has SNR ≈ 9 over eight TESS sectors. Its credibility rests partly on choices made after seeing the data. This note fixes, in advance, the prediction for one new sector of TESS data, the measurement that will be made, and what each outcome will mean. It removes any room to adjust the analysis afterwards. We commit to publishing the result, whatever it is, as a new version of this record within 30 days of the Sector 114 light curves appearing on MAST.

Prediction

Ephemeris from the joint fit in the companion preprint: $P = 5.450138 \pm 0.000016\,\mathrm{d}$, $T_0 = 2458628.6479\,\mathrm{BJD_{TDB}}$ (σ_{T_0} taken conservatively as $0.0073\,\mathrm{d}$), $T_{14} = 2.37\,\mathrm{h}$. Uncertainties use $\sigma_n = \sqrt{\sigma_{T_0}^2 + (n\,\sigma_P)^2}$ and ignore the negative T_0–P covariance, so they are conservative.

Epoch	Mid-transit ($\mathrm{BJD_{TDB}}$)	σ (min)	Mid-transit (UTC, geocentric)	Window (UTC)
518	2461451.81938	15.9	2027-02-15 07:40	06:29–08:51
519	2461457.26952	15.9	2027-02-20 18:28	17:17–19:39
520	2461462.71966	15.9	2027-02-26 05:16	04:04–06:27
521	2461468.16980	16.0	2027-03-03 16:03	14:52–17:14
522	2461473.61994	16.0	2027-03-09 02:51	01:40–04:02
523	2461479.07007	16.0	2027-03-14 13:39	12:28–14:50 (sector edge)

Transits that fall in data gaps or outside the final sector boundaries will be reported and excluded. Predictions for 2026 October – 2027 December, for ground-based observers, are in the accompanying CSV.

Frozen measurement

- **Data:** SPOC 2-minute PDCSAP light curve for Sector 114 if available. Otherwise the TESS-SPOC full-frame-image light curve, which will be stated.

- **Code:** tess-hunt commit `d7c59d1` (`https://github.com/killercatfish/tess-hunt`): the same preparation and detrending as the companion preprint, with TOI-913 b's transits and the TOI-913.02 events masked.
- **Statistic:** the "core depth" D_{114}, the mean depth over the central 60% of each predicted transit relative to the local out-of-transit level. Its error σ_{114} is computed from the scatter of out-of-transit windows in the same sector, as in the pipeline's sector-consistency test, with a 10% systematic floor.
- **Expected:** on the same measure, the eight existing sectors give 225 ± 24 ppm, with typical single-sector errors of ≈ 65 ppm. With the floor, we expect $\sigma_{114} \approx 69$ ppm.

Pre-registered outcomes

Using $D_{\rm exp} = 225$ ppm and the measured σ_{114}:

Outcome	Condition	P if real	P if no signal
Supports	$D_{114} > 2\sigma_{114}$ and $\lvert D_{114} - 225\rvert < 2\sigma_{114}$	0.90	0.02
Inconclusive	otherwise, and not one of the rows below	0.08	0.08
Disfavours	$D_{114} < 225 - 2\sigma_{114}$ (i.e. $\lesssim 87$ ppm)	0.02	0.90
Too deep	$D_{114} > 225 + 2\sigma_{114}$	0.02	≈ 0

The probabilities assume $\sigma_{114} = 69$ ppm and Gaussian errors. A "too deep" result would point to a blend or variability and will be reported as inconsistent with the planet interpretation as stated. Separately, the best-fit common time shift of the Sector 114 transits must lie within ± 48 min (3σ) of the prediction. A larger shift will be reported as an ephemeris failure.

After the pre-registered test, we will also report, as clearly labelled secondary results: the nine-sector refit, the updated SNR, and any changes to the vetting results. A single sector cannot validate the candidate. A "supports" outcome means only that the signal reappeared where and as predicted.
